Plant ecophysiology is concerned largely with two topics: mechanisms (how plants sense and respond to environmental change) and scaling or integration (how the responses to highly variable conditions—for example, gradients from full sunlight to 95% shade within tree canopies—are coordinated with one another), and how their collective effect on plant growth and gas exchange can be understood on this basis.

Physiological ecology integrates the physiology of organisms within the context of their environment and evolutionary histories (McNab, 2002); thus, it bridges this gap between disciplines and enhances conservation efforts by improving our understanding of how physiology influences the distribution and ecology of organisms and our ability to predict the ways in which animals may respond to changes in their environment.
