Near-infrared Fourier Transform Raman spectroscopy (NIR FT-Raman) was demonstrated in a seminal article appearing in 1986, (24) the concept evolved to incorporate the reduction of fluorescence inherent to NIR excitation and the signal-averaging and throughput advantages of the optical interferometer. A Nd:YAG laser provides the NIR excitation, a quartz or other NIR beamsplitter is used in the interferometer and a NIR detector (usually, Indium Gallium Arsenide - InGaAs or Germanium - Ge) is ...

Fourier Transform Raman Spectroscopy - an overview ...

Fourier-transform spectroscopy is a measurement technique whereby spectra are collected based on measurements of the coherence of a radiative source, using time-domain or space-domain measurements of the electromagnetic radiation or other type of radiation. It can be applied to a variety of types of spectroscopy including optical spectroscopy, infrared spectroscopy, nuclear magnetic resonance and magnetic resonance spectroscopic imaging, mass spectrometry and electron spin resonance spectroscopy

Fourier-transform spectroscopy - Wikipedia

Fourier-transform (FT) Raman spectroscopy was used to characterize the organic and mineral components of biological and synthetic calcium phosphate minerals. Raman spectroscopy provides information on biological minerals that is complimentary to more widely used infrared methodologies as some infrared-inactive vibrational modes are Raman-active.

Fourier Transform Infrared Spectroscopy (FTIR) is a vibrational technique that measures the absorbance, transmittance, and reflectance of infrared radiation resulting from its interaction with the gem.

Advantages and Disadvantages of Raman & Fourier Transform ...

Fluorescence and initiation of photoreactions are problems frequently encountered with resonance Raman spectroscopy of photobiological systems. These problems can be circumvented with Fourier-transform Raman spectroscopy by using the 1064-nm wavelength of a continuous wave neodymium-yttrium/aluminum-garnet laser as the probing beam.

Fourier transform infrared (FTIR) spectroscopy and Raman spectroscopy are chemical analytical methods that have also been used to collect information about whole bacterial cells (14). The outputs from these methods are FTIR and Raman spectra that contain signals from the organic functional groups in the sample.

While FT-IR spectroscopy is sensitive to functional groups of these polysaccharides, i.e. hydroxyls, carboxyls, esters and amides, FT-Raman spectroscopy, is better at analysis complex skeletal vibrations of polysaccharide chains, i.e. glycosidic bonds and pyranoid rings.

Fourier transform Raman spectrometers were developed as late as in 1986 due to the reasons discussed herein. [6,7] It is known that shot noise dominates the noise of visible detectors, i.e. for an...

Fourier-transform infrared spectroscopy (FTIR) is a technique used to obtain an infrared spectrum of absorption or emission of a solid, liquid or gas. An FTIR spectrometer simultaneously collects high-spectral-resolution data over a wide spectral range. This confers a significant advantage over a dispersive spectrometer, which measures intensity over a narrow range of wavelengths at a time.

We compared the two most promising techniques for MP analysis, namely, Raman and Fourier transform infrared (FTIR) spectroscopy, by analyzing MPs extracted from North Sea surface waters. Microplastics >500 µm were visually sorted and manually analyzed by µ-Raman and attenuated total reflection (ATR)-FTIR spectroscopy.

Fourier transform Raman spectroscopy is used to probe these chemical changes under a range of experimental conditions. Monomer consumption and polymer formation curves are constructed by cross-correlating relative Raman peak intensities for spectra acquired on individual gel samples which have each been irradiated to known doses.

Abstract Detailed Fourier transform Raman spectra of fluconazole have been recorded and the main spectral features of fluconazole have been assigned to its vibrational modes. Two different polymorphic forms of fluconazole were identified in two spectral regions, 150–1700 cm⁻¹ and 2700–3200 cm⁻¹, respectively.

In the present work, safflower red was analyzed by Fourier transform (FT)-Raman and surface-enhanced Raman scattering (SERS) spectroscopies and the band assignment was carried out with the support of density functional theory calculations. Different pH values were tested in order to determine the optimal conditions for SERS analysis.

The spectral resolution of broadband Fourier-transform coherent anti-Stokes Raman spectroscopy is limited by the maximum optical path length difference that can be scanned within a short time in an interferometer. However, alternatives to the Fourier transform exist which can bypass this limitation with certain assumptions.
