From wiki.gis.com. Jump to: navigation, search. Terrain Analysis is the analysis and interpretation of topographic features through geographic information systems. Such features include slope, aspect, viewshed, elevation, contour lines, flow, upslope flowlines and downslope flowlines. The intention is to build mathematical abstraction of surface terrain in order to delineate or stratify landscapes and create an understanding of relationships between ecological processes and physical features.

From the ArcView Help files, here is the way in which slope is calculated, which is a weighted two-directional slope (same in ArcGIS?). The actual algorithm that is used to calculate slope is: $\text{rise_run} = \sqrt{(\text{SQR}(\text{dz}/\text{dx}) + \text{SQR}(\text{dz}/\text{dy}))}$ $\text{degree_slope} = \text{ATAN}(\text{rise_run}) * 57.29578$

A digital elevation model (DEM) is a digital representation of ground surface topography or terrain. It is also widely known as a digital terrain model (DTM). While the term can be used for any representation of terrain as GIS data, it is generally restricted to the use of a raster grid of elevation values.

A digital elevation model is a bare-earth raster grid referenced to a vertical datum. When you filter out non-ground points such as bridges and roads, you get a smooth digital elevation model. The built (power lines, buildings and towers) and natural (trees and other types of vegetation) aren't included in a DEM. Digital Elevation Model (DEM)
