Sexual Selection in Primates. In most primate species, the distribution of food in the environment determines the distribution of females, and the distribution of females determines the distribution of males. When food is so dispersed that females do best by foraging on their own, males disperse to pair up with the lone females.

Paradoxically, sexual size dimorphism is biased towards males in most mammalian species. An accepted explanation is that sexual dimorphism in mammals evolved by intramale sexual selection. I tested this hypothesis in primates, by relating sexual size dimorphism to seven proxies of sexual selection intensity: operational sex ratio, mating system, intermale competition, group sex ratio, group size, maximum mating percentage (percentage of observed copulations involving the most successful male

Sexual selection In primates, sexual dimorphism including body size, canine tooth size, and morphological characteristics is often attributed to sexual selection, which is believed to act through two mechanisms: intrasexual competition and female mate choice.

Sexual dimorphism in non-human primates - Wikipedia

It has been observed that male primates will attempt to monopolise, or gain exclusive sexual access to, a female early on in the duration of sexual swellings to ensure he has sexual access at maximum swelling when she is most likely to be ovulating.

Sexual swelling - Wikipedia

-Intersexual selection does not play a significant role in primates. -Sexual selection results in male adaptations that enhance their ability to compete with other males for access to females.
-Intrasexual selection favors traits that increase success in male-male competition. -Sexual selection is not as strong as ordinary selection.
