The active front end monitors the input current waveform and shapes it to be sinusoidal, reducing total harmonic distortion (THD) to 5 percent or less. (Note that THD is only measured for lower-order harmonics. An LCL filter is necessary to reduce higher-order harmonics caused by the switching frequency of the IGBTs.)

Construction and benefits of an active front end (AFE) drive

The Active Front End acts as a controlled rectifier. Being a current-controlled inverter + filter, if the currents are controlled to be sinusoidal signals in phase (or in opposition) to the grid voltage, the result is power factor close to unity and low-order harmonics controlled to nearly zero. On the other hand, DC bus capacitor voltage is controlled by regulating the amplitude and direction ...
